

ABSTRACT OF THE DISCLOSURE

In a system and method for remote maintenance, remote configuration and/or remote operation of an electrophotographic printing or copying system, a data processing system is connected with a communication unit of the printing or copying system via a network. Given a deactivated printing or copying system, the communication unit receives first data transmitted by the data processing system via the network and processes the transmitted first data. After receiving the first data, the communication unit activates a data processing unit of the printing or copying system. After the activation of the data processing unit, second data can be transmitted between the data processing system and the data processing unit.
